## 45 W POWER AMPLIFIER

Figure 1.
Block Diagram

## 1. DESCRIPTION

Motorola's TLD1600A Series Power-Amplifiers provide the following features:
-- A minimum of 45 W RF output.
-- All circuitry except power transistors contained on one single-sided circuit board.
-- Power transistors mounted directly to (but electrically isolated from) the heat sink.
-- RF connections made through two coaxial connectors which plug directly into the input and output filter assemblies located below the heat sink shelf.
-- DC power supplied via two feed-through capacitors that also provide filtering.
-- Input, outputand all other interstage matching (with the exception of a single fixed-tuned matching network between the controlled amplifier stage and the driver stage) is accomplished by the use of rf transformers wound around ferrite cores. Only one tuning adjustment is required due to the relatively broadband matching characteristics of the ferrite transformers and the low inductance leads of the silicon opposed emitter transistors.
-- One metering socket which is zccessible from the component side of the circuit board allows three major test points to be monitored and permits measurement of the dc current drawn by the final amplifier stage.
-- Due to the heat sink mounting requirements for this board, servicing is accomplished from the component side of the board.
-- Diode protection against reverse polarity voltage (board mounted diode).
-- Output protection provided by current limiter transistor driven by power control circuit.
(Controls gain of the first stage.) Single-wire w/push-on connector provides interconnection between power control and PA circuitry.
-- No high voltage required; operates directly from 12-volt battery.

## 2. FUNCTIONAL OPERATION

Refer to the block diagram, Figure 1, and the schematic diagram. This series of power amplifier requires a 400 mW rf input from the exciter board. This inputis passed through a bandpass filter assembly and a ferrite step-down transformer (to match the input impedance to the first stage) to the gain-controlled amplifier stage. The external power control circuit which drives the currentlimiter transistor determines the gain of this stage. The power control circuit monitors the output of the final stages of the power amplifier, the load condition and the heat sink temperature.

The output of the gain controlled amplifier is passed through a fixed-tuned broadband, matching network and applied to the driver stage. A second ferrite transformer is utilized to match the singleended output of the driver stage to the input of the push-pull power amplifier stage. The output from the final stage is stepped up in impedance by ferrite transformer and paralleled to provide the 50 -ohm output impedance to match the input impedance of the harmonic filter.

Pin 1 of the metering receptacle provides a means of checking the incoming signal from the exciter. Pin 2 permits observation of the drive output of the first stage and an indication of the operation of the driver stage. Pin 3 reflects the drive signal and operation of the two push-pull power amplifier stages. Reference position $A$ on the Motorola Portable Test Set uses pin 7 of the metering socket as an A+reference against which the outputs of pins $1,2, \& 3$ are checked. Switch the test set to reference position $B$ which uses pin 6 as a reference and then switch to meter
position 5. This provides a reading across a calibrated resistor through which the current is drawn by the final amplifier stages.

## 3. MAINTENANCE

a. General

## NOTE

Because of the complexity involved and time required to remove the PA board, compared to plug-in boards, it is not recommended that the PA board be removed. Proper troubleshooting techniques will usually locate defective components "on the spot". Removal and replacement instructions, however, are given in the event removal is necessary.

This section of the manual provides the maintenance shop procedures for the PA board. It assumes that preliminary tests have already localized the trouble to the PA board. These procedures include measurements with a Motorola portable test set, a vom, a complete set of performance tests and extensive troubleshooting procedures.

## CAUTION

The PA board must be installed in a radio set for testing to provide the necessary power, ground control, heat sinking and signal connections.

## b. Recommended Test Equipment

The following test equipment is the minimum required for troubleshooting and adjus ting the PA. All such equipment is battery operated which permits testing to be performed in the field where no commercial power is available for bench type test equipment.
(1) Motorola Sl056A through S1059A Portable Test Set and Model TEK-37 or TEK-37A Adapter Cable. The portable test set is required for checking each stage for proper operation.
(2) A Motorola Solid-State DC Multimeter or a 20,000 ohm-per-volt multimeter should be used, however a low impedance multimeter is acceptable for dc voltage measurements only.
(3) Motorola T1013A RF Load Resistor (dummy load) or equivalent.

## CAUTION

For bench testing, use only a power supply that will provide terminal voltage of 13.4 volts under full load with the transmitter keyed, but not exceed 16.5 volts (including transients) when switched to the no load (unkeyed) condition. Most power supplies will not meet this requirement; in fact, some SCR regulated power supplies have transient response that allows the output voltage to momentarily triple when switched from full load to no load. The following bench supplies are approved for testing the 'Micor" radio:
Motorola S1303A or Sl305A Regulated, Power Supply

Motorola Tl261A Transistorized 24-Volt to 12-Volt Converter driven by a Motorola T1012A Power Supply

12-Volt audomotive battery with Motorola Tl012A Power Supply used as a battery charger.

## c. Test Set Metering

The PA is equipped with a metering receptacle which allows four major test points to be measured. on a Motorola portable test set. The portable test set can be connected to the PA metering receptacle and readings made at each of the-test points by merely rotating a selector switch on the test set. A failure in almost any portion of the PA will produce a low or zero meter reading for one or more of the test points. Improper alignment will also cause improper meter readings.

To make the measurements, the portable test set must be connected to the radio setas shown in Figure 2 and listed in the following procedure.
(1) Set the function selector switch of the portable test set to the XMTR position.
(2) Set the meter reversing switch of the test set to the METER REV position, the selector switch to position 1 and reference switch to position A.
(3) Connect the 20 -pin meter cable plug to the test set. When the test set is not in use, disconnect the 20 -pin plug to conserve battery life. The plug acts as an on-off switch completing the battery circuit.

Figure 2.
PA Metering Test Set－Up
（4）Connect the red＂control＂plug of the adapter cable to the receptacle on the control circuit board of the radio set．Connect the white ＂metering＂plug of the adapter cable to the receptacle on the PA circuit board．
（5）The entire transmitter is necessary for testing PA boards including the power control board for proper control．
（6）The output of the radio must be terminated in one of three types of loads：

> -- The antenna load.
－－A dummy load such as Motorola＇s
T1013A RF Load Resistor．
－An＇RF wattmeter．

## NOTE

A dummy load is preferred to the antenna to eliminate the possibility of shutback by the power control board due to a defective antenna．
（7）Connect power to the radio set cable．If the radio set is installed in a vehicle，it may be
desirable to start the engine to keep the battery fully charged during testing．
（8）Set the ON－OFF switch of the radio＇s control head to ON．
（9）Key the transmitter with the XMTR ON button on the test set．Observemeter l．Unkey the transmitter．
（10）Set the selector switch to positions 2 \＆ 3 ，then switch to reference position $B$ and switch to meter position 5 respectively，keying the trans－ mitter and observing the meter reading for each． On multi－frequency radio sets，repeat the read－ ings for each exciter frequency．An analysis of the meter readings for determining whether each circuit is good or bad follows：

Each time maintenance is performed on the PA，the readings should be compared with the previous set of readings．Any degradation of performance will quickly be noted．Often，a lower reading may indicate an impending failure and corrective action may be taken before the circuit fails entirely．

## d. Performance Tests

(1) No performance test of the power amplifier is required other than rf power output from the radio as a whole. Before checking power output:
(a) The exciter board should be known to be operating normally.
(b) The power control board should be known to be functioning normally.
(c) The antenna switch should be known to be functioning normally.
(2) Key the transmitter and observe power out which should be 45 watts.
(3) If necessary, adjust POW ER SET control for rated power output.
e. Removal and Replacement

Refer to Figure 3 for instructions to remove and replace the PA circuit board. The PA shield must always be in place during operation of the radio set and should be kept in place as much as possible while testing and troubleshooting. The circuit board must always be secured in place with all mounting screws. The transistors (including the control transistors mounted on the inner wall) must be secured in place to provide proper heat sinking, and the feedthrough connectors must be soldered in place to provide dc power and good rf grounding.

## 4. TROUBLESHOOTING

If a problem has been localized to the PA deck, several checks can be made prior to extensive troubleshooting.
a. Visual

Visually check for obvious physical defects such as broken leads, broken plating, broken or disconnected components or overheated parts. Before any attempt is made to change parts, the circuit should be checked to insure that the problem causing the original failure has been identified and corrected, otherwise damage to the new part may occur.

## b. Voltage Checks

Check for A+ and A- at the feedthrough connections and for proper voltages at the collectors of each transistor. Certain defects such as broken plating, broken leads etc. may not be obvious to a visual inspection.

## c. Troubleshooting

If test set readings are abnormal or tests indicate subnormal performance, logical troubleshooting procedure is required to isolate the defective component efficiently. The accompanying troubleshooting charts summarize these results in a logical sequence. A few voltage and resistance checks in the suspected circuit should readily isolate the defective component. Note that all power for the circuits in the

PA is from A-referenced to A+ (not to chassis ground, this feature allows operation from positive or negative ground power sources).

## CAUTION

Due to the voltage requirements of $P-N-P$ transistors, all "RF ground" plating is A+ and is "hot" with respect to chassis ground in negative ground vehicles. Because of this, caution should be used to prevent connection of "ground" plating on the PA board to chassis ground either directly or by the use of test equipment ground leads. If ac operated test equipment is used, the ground lead must not be electrically connected to ac line ground.

The schematic diagram of the PA board contains the voltage readings required for troubleshooting. The readings are typical for normal operating conditions at rated power output for the radio. Refer to troubleshooting charts and the schematic when a defect is suspected in the PA board.

## 5. PA REPAIR NOTES

a. Resistance Measurements of Transistors in Push-Pull Pairs

Due to the fact that transistors in push-pull pairs are dc connected at both base and emitter, BOTH devices should be measured when a defect in the pair is suspected.

## b. Transistor Removal Procedure

(1) Unscrew both mounting screws from the base of the transistor. The nuts for the mounting screws on the reverse side of the shelf are captivated and will not fall out.
(2) Remove excess solder from around transistor tabs with a vacuum bulb type desoldering device.
(3) Gently lift each lead, one at a time while applying heat.
(4) When all four leads are loose from the board, carefully lift out the transistor.

## c. Transistor Installation Procedure

(1) Pre-tin underside of each transistor lead.
(2) Apply a light coat of Wakefield Thermal Compound to the underside of the transistor mounting base and to the heat sink.
(3) Install the transistor making sure that all collector leads except on Q501, face the front of the radio. The collector lead of Q50l faces the inner wall of the radio. Refer to the circuit board detail.
(4) Screw down the two mounting screws securely.
(5) Solder each transistor lead one at a time to the circuit board. The use of a generous amount of solder will insure good contact of the entire tab to the board. Use care that solder does not bridge to other plating or that solder does not flow into the cutout in the circuit board.

## d. Procedure for Resistance Measurements of Transistors

(1) Set ohmmeter to RX1, RX10, or RX100 scale. (preferably RXIO if available).
(2) Measure the resistance from lead to lead as described:
(a) With the positive probe on the base no indication (very high impedance) should be observed when the negative probe is touched to the collector or emitter. (Reversedropmeasurement.)
(b) With the negative probe on the base, a relatively low impedance should be observed when touching the positive probe to the collector and emitter. (Forward drop measurement.)
(c) No indication should be observed from collector to emitter regardless of the polarity of the ohmmeter probes.

Should any indication be observed in measurements (a) or (c), the transistor is defective and should be replaced.

REPLACEMENT PROCEDURE
10. REPLACE BOARD MAKING SURE CONNECTORS AND HOLES ARE LINED UP
11. REPLACE MOUNTING POSTS
. REPLACE CONTROL TRANSISTOR, WASHER, AND INSULATOR IN CORRECT
order.
. PlUG in Control lead.
15. IF TRANSISTORS WERE REMOVED, REPLACE AS SHOWN; INSERT AND TIGHTEN SCREWS BEFORE RESOLDERING TABS

UNSCREW 8 SCREWS FROM TRANSISTOR MOUNTING BASES BOTTOM SIDE OF HEAT SINK.

## EXCERPTS FROM FCC REGULATIONS

FCC Regulations state that:

1. Radio transmitters may be tuned or adjusted only by persons holding a first or second class commercial radiotelephone operator's license or by personnel working directly under their immediate supervision.
2. The power input to the final radio frequency stage shall not exceed the maximum figure specified on the current station authorization. This power input shall be measured and the results recorded:
a. When the transmitter is initially installed.
b. When any change is made in the transmitter which may increase the power input.
c. At intervals not to exceed one year.
3. Frequency and deviation of a transmitter must be checked:
a. When it is intially installed.
b. When any change is made in the transmitter which may affect the carrier frequency or modulation characteristics.
c. At intervals not to exceed one year.

## COMPLETE POWER AMPLIFIER ALIGNMENT PROCEDURE <br> 45/60/90/110 WATTS

NOTE: Portable Test Set meter sensitivity switch should be on 100 mV for all readings.

| STEP | A DJUST | METERING PLUG LOCATION | TEST SET SWITCH POSITION | $\begin{aligned} & \text { REF. \& METER } \\ & \text { REV. SWITCH } \\ & \text { POSITION } \end{aligned}$ | PROCEDURE |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 |  |  |  |  | Turn the POWER SET control fully countèrclockwise (minimum power output). If the power amplifier is to be realigned less than $\pm 1 \mathrm{MHz}$, proceed with Step 2. Otherwise, prealign the board by setting C50l fully clockwise and C502 fully meshed. |
| 2 | POWER <br> SET <br> (R611) | POWER CONTROL BOARD | Wattmeter or 1 | METER REV. REF. A | Key transmitter and slowly turn POW ER SET control clockwise until rated power is attained or until no further increase in power output is observed. |
| 3 | $\begin{aligned} & \text { POWER } \\ & \text { SET } \\ & \text { C501 } \\ & * \text { C502 } \end{aligned}$ | POWER CONTROL | 5 | METER REV: REF. B | Adjust C501, then C502, for a dip on meter 5. If a dip cannot be found, reduce POWER SET until meter 5 is less than 20 uA . |
| 4 |  | POW ER CONTROL BOARD | Wattmeter or 1 | METER REV. REF. A | Repeat Steps 2 and 3 until rated power is reached. Proceed to Step 7 when rated power is attained and meter 5 is less than 30 uA . If rated power cannot be reached and meter 5 is less than 30 uA proceed with Step 5. <br> If at this point meter 5 is greater than 30 uA and rated power has not been attained, refer to the power control troubleshooting chart. |
| 5 | R610 | POW ER CONTROL | Watmeter or 1 | METER REV. REF. A | Remove the power control board shield. Use tuning tool \#66A82846D01, or equivalent, to adjust R610. Access to this control is provided by a small slot located approximately $3 / 4$ inch from the POWER SET hole, toward the rear of the radio. Use the tuning tool to rotate the outer edge of the serrated knob toward the heat sink until either rated power is attained or no further increase in power output is observed. Replace power control shield. |
| 6 |  |  |  |  | Repeat Steps 3 and 4. |

* C502 is used only on $90 / 110$ watt models.
